# Chapter Two—Population Synthesizer

# 1. INTRODUCTION

#### 1.1 Overview

Because TRANSIMS is based on the movement of individual travelers between activities at different locations, it must create a synthetic population that represents every individual in the metropolitan region under study. Population demographics are crucial in creating reality-based simulations because such demographics determine the level of activity for each household.

Demographic examples include the individual's age, income, gender, and employment status. Such demographics determine how each individual travels across the transportation network. For example, a six-year-old girl will take the bus to school, whereas a 30-year-old executive will carpool to work.

The procedures outlined in this chapter generate a baseline 1990 synthetic population and provide methods that can update this population to a future year. At this time, the update methodology requires forecast demographics in the exact format as used by Portland Metro. This will change in future releases of this technology.

## 1.2 Source Data

To create a virtual population, the Population Synthesizer requires the following types of source data:

- U.S. Census Bureau Summary Tape File 3A (STF-3A) data<sup>1</sup>,
- U.S. Census Bureau Public Use Microdata Samples (PUMS)<sup>2</sup>
- Master Area Block Level Equivalency/Geographic Correspondence Engine (MABLE/Geocorr), and
- Forecast marginal demographic data.

#### 1.2.1 STF-3A Data

These files contain demographic summary tables from the 1990 Census for small geographic areas, census tracts, or census block groups. Mostly one-dimensional, these summary tables contain information such as the distribution of the age of the householder or the number of workers in the family. Table 1 and Table 2 show typical STF-3A data.

n	4	134	94	46	46	36	0

#### 1.2.2 PUMS

Census tracts or block groups that are combined into much larger geographic areas are known as Public Use Microdata Areas, or PUMA. Microdata in each PUMA, the PUMS, consist of a 5% sample of the complete census records for the PUMA. PUMS contain the complete structure of each household, including the number of people in a given household, the household income, number of workers, and number of vehicles owned. These files are edited to protect the confidentiality of all individuals, but they have the information necessary to conduct effective research and analysis.

#### 1.2.3 MABLE/Geocorr

The MABLE/Geocorr search engine supports data maintained by the Center for International Earth Science Information Network (CIESIN) at Columbia University. The data and search engine are available at the following Internet site:

http://plue.sedac.ciesin.org/plue/geocorr

The combined data set and the search engine yield a correspondence between PUMAs and census block groups

# 1.2.4 Forecast Marginal File

When creating a forecast population, the Population Synthesizer requires a "Forecast Marginal File" as input. This file contains the forecast marginal distributions, like those given above in Table 1, for household size, householder age, and household income as a function of census tract and block group.

This file must be created outside the TRANSIMS Framework; forecasts can typically be obtained by transportation planning agencies.

Volume Three—Modules 08 January 2003 3

# 1.3 Using the Data

TRANSIMS uses an algorithm developed by Beckman, Baggerly, and McKay<sup>3</sup> to generate synthetic populations from the four data sets described above. Land-use data are used to place individual households at activity locations along the transportation network. A complete description of the algorithm appears in Section 4 (*Algorithm*).

Chapter Two—Population Synthesizer

Volume Three—Modules 08 January 2003 4

# 2. MODULE DESCRIPTION

## 2.1 Overview

Fig. 1 shows the types of data the Population Synthesizer uses to generate a synthetic population of households that contain individual demographics and household locations within the TRANSIMS Network.

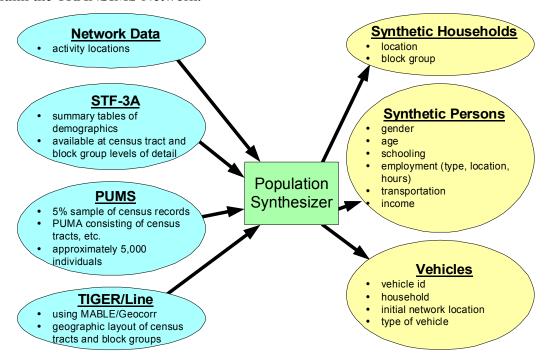

Fig. 1. The Population Synthesizer takes in various types of census data to generate synthetic households, individuals, and vehicles.

# 2.2 Defining a Household

In the baseline methodology presented here, each household in a synthetic population is classified as either family, non-family, or individuals living in group quarters such as dorms. At a minimum, each household must contain at least one person; family households contain one or more adults and possibly children. Household demographics vary in accordance with source data and study needs.

# 2.2.1 Using Households

TRANSIMS assigns households to activity locations on a link of the TRANSIMS Network. Each activity location is assigned to a link on the network and is associated with the land-use characteristics that surround it. Multiple households can be assigned to one activity location.

## Example:

An activity location on a link can represent one side of a street, whereas a second could represent activities taking place on the other side. Moreover, activity locations could represent individual buildings on a street, or one activity location could represent all activities that take place on the street.

Synthetic populations in essence "drive" the Activity Generator, which uses the data to create individual travel activities, such as work, school, or a shopping. Population data also can be used to categorize and filter population subsets used for various types of equity analyses.

# 2.3 Data Format

Any viable source of household and demographic data can be used to construct a synthetic population, provided that the output of the computation is formatted in accordance with TRANSIMS data formats for synthetic populations.

# 3. GENERATING A SYNTHETIC POPULATION

**Step One** • Identify an appropriate PUMA.

Use MABLE/Geocorr to obtain a list of block groups within the PUMA.

**Step Two** Obtain summary statistics from STF-3A for each of the block groups identified in the PUMA.

## Example:

Summary data could include the householder's age, the family's income, type of family (single parent, divorced, etc.), and number of workers in the household.

- **Step Three** Construct a multidimensional table from the PUMS data.
  - Make sure that the dimensions correspond with STF-3A summary statistics.

Note: Fig. 2 represents these steps in graphic form.

#### Example:

In Fig. 2, the multidimensional table would have four dimensions that correspond to four classifications: householder's age, the family's income, type of family, and number of workers in the household.

Each household in the PUMS has a household weight. The sum of these weights for each of the households in the PUMS for each classification compose the multidimensional table.

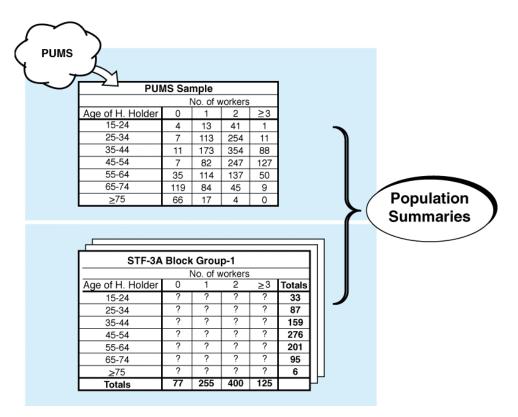

Fig. 2. TRANSIMS uses various data types to generate a synthetic population. Note that these data have been modified to ensure anonymity.

#### Step Four •

- At this point, the proportion of households for each block group's classification is unknown. To determine this, TRANSIMS uses a twostage iterative proportional fitting procedure outlined by Beckman, Baggerly, and McKay<sup>4</sup>.
- This procedure satisfies the distributions of the STF-3A data for each block group while maintaining the correlation structure of the table constructed from the PUMS

# **Step Five** • The block groups are updated for a forecast.

- Iterative proportional fitting uses the correlation structure of the generated block group demographic tables and the STF-3A type forecast demographics for the update.
- **Step Six** Select households from the PUMS to match the number of households in the Census over a given geographic area, such as a block group or a census tract.

<sup>&</sup>lt;sup>4</sup> See Footnote 3.

• Use land-use information to place each household within a block group at an activity location.

<u>Note</u>: A baseline population for the census year can be generated by skipping Step Five.

Note: Land-use data are stored in the network activity location files. At a minimum, these files contain the identity of the activity locations, their locations, the corresponding block group and census tract, and some indication of the activities that may be performed at that location.

Fig. 3 shows this step graphically.

- Identify the activity locations within a block group before placing households from the synthetic population at an activity location.
- Using land-use data, determine a weight for each activity location. These weights are proportional to the probability that a household will be placed at the activity location. The weights could be formed, for example, by adding the single family residential square footage to the multiple of the multifamily square footage for each activity location. In another approach, the number of households on a block could be determined from phone books and used as the weights.
- Divide each individual weight for an activity by the total weight of all the activity locations in the block group.
- The resultant ratios are used as the probability of a household being located on a link.
- For each synthetic household, a random activity location (based on the probabilities) is selected; the household is then placed at that activity location.

<u>Note</u>: Households need not be placed at unique activity locations. Many households can share the same activity location.

• The household location algorithm can remain the same no matter which area is being studied. However, the weights given to the activity locations in a block group will depend on the quality and availability of land-use data.

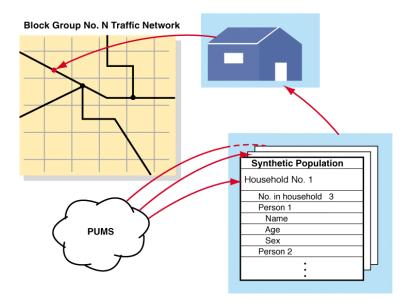

Fig. 3. Creating households and placing them on the network involves randomly selecting actual PUMS households in accordance with the proportions derived from the Iterated Proportional Fitting method.

# 3.1 Other Techniques

Households may be located on a link by other techniques.

#### Example 1:

A census block could be used to determine the number of households in a block. This number could then be associated with an activity location and used as the weight.

#### Example 2:

Electronic phone books or aerial photography could be used to determine the number of households in a block.

<u>Note</u>: To date, neither of these techniques has been used during a TRANSIMS case study.

# 3.2 What About Vehicle Ownership?

To assign vehicle ownership, TRANSIMS currently uses the number generated from the synthetic population procedure using the PUMS or just assigns every possible driver a vehicle. A more refined vehicle ownership model based on population demographics and network characteristics could be implemented and called in the Framework after the synthetic population has been generated.

In traditional methods, household vehicle ownership has been a factor in the choice of transportation modes. Given the TRANSIMS iterative methods to determine the traveler's mode of transportation using the iteration database and the Selector, a refined vehicle ownership model is not necessary.

In either case, each vehicle represents an entry in a vehicle file. This file contains the TRANSIMS vehicle identification number, the household to which it is assigned, and the vehicle emissions type. The emissions type is used in the Emissions Estimator module to determine emissions. It reflects the operating condition of the vehicle, its type, and age.

Presently, these vehicle types are assigned at random according to a national or local distribution of 23 vehicle emission types described in Volume Three (*Modules*), Chapter Seven (*Emissions Estimator*). In the future, an analyst may wish to use a vehicle type model based on Department of Motor Vehicle statistics, inspection and maintenance records, and the synthetic population.

# 4. ALGORITHM

## 4.1 Overview

Fig. 4 shows the data flow used to create, locate, and assign vehicles to a complete synthetic population of households and individuals.

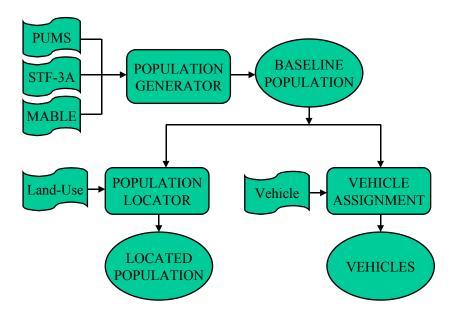

Fig. 4. This flowchart shows the process used to create, locate, and assign vehicles to a complete synthetic population and individuals.

# 4.2 Baseline Population Synthesizer

Of the processes shown in Fig. 4, the baseline Population Synthesizer is the most complex. Its objective is to create a population over small geographic areas of census groups that maintain the statistical characteristics of the census. However, as shown in Table 3, the summary data for block groups from STF-3A do not give the entries for any cross-classified demographics.

Table 3. The cross-classification of the number of workers and the age of the householder for census tract 1, block group 2 of Los Alamos County, NM, is unknown.

Householder Age								
Workers	15-24	25-34	35-44	45-54	55-64	65-74	>74	Total
0	?	?	?	?	?	?	?	0
1	?	?	?	?	?	?	?	121
2	?	?	?	?	?	?	?	214
>2	?	?	?	?	?	?	?	25
Total	44	134	94	46	46	36	0	

A synthetic population is easily generated if cross-classified tables exist for small areas such as block groups. Because PUMS contains complete household records, these could be drawn at random, thus satisfying the cross-classified table for the block group. This is the general scheme for the algorithm presented in this document, except that the cross-classified table for the block groups is estimated. This estimation process satisfies the totals as given by STF-3A.

The general methodology consists of three steps.

**Step One** Select a reasonable set of demographics from STF-3A that characterize the population.

**Step Two** For each block group, estimate the proportions in the cross-classified table made up of the demographics selected in Step One.

**Step Three** Draw households at random from the PUMS corresponding to the block group so that the estimated proportions in the cross-classified table are satisfied.

# 4.3 Multiway Summary Tables

Although cross-classified tables cannot be derived from STF-3A for small areas, multiway summary tables can be created for the entire PUMA area. For example, block group 2 of census tract 1 for Los Alamos County, NM, is contained in PUMA 00400. Table 4 provides the multiway table for this PUMA. It shows the number of workers in a family and the age of the householder.

Volume Three—Modules 08 January 2003 13

Table 4. The cross-classification of the number of workers and the age of the householder for PUMA 00400, which contains census tract 1, block group 2 of Los Alamos County, NM.

Householder Age								
Workers	15-24	25-34	35-44	45-54	55-64	65-74	>74	Total
0	2	11	9	3	26	64	42	157
1	11	108	122	48	80	61	18	448
2	28	135	274	156	85	22	6	706
>2	0	3	65	76	40	10	3	197
Total	41	257	470	283	231	157	69	

To estimate the proportions in the cells of the multiway block group tables, TRANSIMS uses iterative proportional fitting<sup>5</sup> (IPF) of the block group summaries to the cross-classified values in the PUMS. IPF ensures that the correlation structure of the demographics for every entity that contributes to the PUMA (e.g., block groups) is the same as the correlation structure in the multiway tables constructed from the PUMS.

IPF assumes that we have

- 1) a sample from a multiway classification of characteristics, and
- 2) the exact totals for the margins of the multiway table.

In this case, we could assume that the PUMS represents the sample and the STF-3A data give the marginal totals. We show later that this is an oversimplified view of these data, but we continue with this to better explain IPF.

IPF estimates (i.e., refines) the entries in the sample multiway table (in this instance, the PUMS) to make them exactly match the known marginals (in this case, the STF-3A summary data) while maintaining the sample table's correlation structure. The algorithm is exceedingly simple. The algorithm begins by converting all summaries and tables to proportions of the total. For example, Table 3 and Table 4 become Table 5 and Table 6, respectively. In terms of proportions, the PUMS sample for these two demographics is shown in Table 7.

Table 5. Proportion of workers in family households for census tract 1, block 2 of Los Alamos County, NM.

Proportion o	of Family Househol	lds, <i>n</i> , with Numbe	er of Workers in th	e Household
Workers	0	1	2	>2
Prop.	0.000	0.336	0.594	0.069

<sup>&</sup>lt;sup>5</sup> Deming, W.E. and Stephan, F.F. (1940), On A Least Squares Adjustment Of A Sampled Frequency Table When The Expected Marginal Tables Are Known, *Annals of Mathematical Statistics*, Vol. 11, pp 427-444.

Age	15-24	25-34	35-44	45-54	55-64	65-74	>74
Prop.	0.011	0.372	0.261	0.128	0.128	0.100	0.000

Table 7. Cross-classification of the proportion of workers and the age of the householder for PUMA 00400, which contains census tract 1, block group 2 of Los Alamos County, NM.

	Householder Age							
Workers	15-24	25-34	35-44	45-54	55-64	65-74	>74	Total
0	0.001	0.007	0.006	0.002	0.017	0.042	0.028	0.104
1	0.077	0.072	0.081	0.032	0.053	0.040	0.012	0.297
2	0.019	0.090	0.182	0.103	0.056	0.015	0.004	0.468
>2	0.000	0.002	0.043	0.050	0.027	0.007	0.002	0.131
Total	0.027	0.170	0.312	0.188	0.153	0.104	0.046	

IPF converts the PUMS proportions in Table 7 so that they have the same row and column proportions as the STF-3A data given in Table 5 and Table 6. IPF accomplishes this by first changing the rows then the columns according to the following rules:

- Update the first row of Table 7 by multiplying each entry by the first marginal proportion for that row given in Table 5 and dividing by the total for that row on the last iteration. In this case, the first element of the first row of Table 7 becomes 0.001\*0.000/0.104=0.000.
- This process continues with the remainder of the rows of Table 7, where (for example) the third entry of the second row becomes 0.081\*0.336/0.297=0.092.

After all the rows are updated, the same procedure is applied to each column. The procedure continues by alternating between rows and columns until the table entries no longer change. For tables with more than two dimensions, the same procedure is followed—updating one dimension at a time. Table 8 shows the final results of this procedure, based on the data in Table 7.

If required, the forecast procedure updates these tables. In either case, the last step in household generation is to draw samples from the PUMS. There are 360 family households in the block group given below. For this block group, 360 households are generated—one at a time—following this procedure:

- First, a category of age and the number of workers are selected at random according to the probabilities in Table 8.
- And second, given the category (e.g., a householder between 45 and 54 years of age in a household with two workers), one of the households in the PUMS matching these demographics is drawn at random. In this case, one household would be drawn from the 156 households possible (as shown in Table 4).

Volume Three—Modules 08 January 2003 15

This process is repeated 360 times to form a population that matches the census. Note that the same household from the PUMS may be selected multiple times by this procedure.

Table 8. Estimated cross-classification of the proportion of workers and the age of the householder for families in census tract 1, block group 2 of Los Alamos County, NM.

Householder Age								
Workers	15-24	25-34	35-44	45-54	55-64	65-74	>74	Total
0	0.000	0.000	0.000	0.000	0.000	0.000	0.000	0.000
1	0.003	0.141	0.061	0.020	0.047	0.063	0.000	0.336
2	0.009	0.228	0.178	0.086	0.065	0.030	0.000	0.594
>2	0.000	0.003	0.022	0.022	0.016	0.007	0.000	0.069
Total	0.011	0.372	0.261	0.128	0.128	0.100	0.000	

Tables 1, 3, and 4, as well as the paper by Beckman, Baggerly, and McKay<sup>6</sup>, show that fitting only one block group at a time using IPF is not entirely correct. IPF is based on the assumption that the seed proportions (as given by the PUMS, Table 7) are a sample of the population that produces the exact marginal totals given by STF-3A (shown here in Table 7). Table 1 shows there are no households with 0 workers in the block group, while Table 4 shows many 0-worker households.

The PUMS consists of a sample of households that contain all or parts of multiple block groups. In this case, block group 2 of census tract 1 from Los Alamos County is just one of the many block groups in PUMA 00400. PUMA 00400 contains all of the block groups in Los Alamos and Santa Fe counties of New Mexico. That PUMA 00400 is a sample of multiple block groups is evident from PUMS.

# 4.4 Creating the Population

TRANSIMS uses the following steps to construct a true synthetic population. A two-step procedure is used to modify the IPF routine so that it can simultaneously consider all block groups that make up a PUMA. A final step is added to take into account the forecast marginal inputs.

Step One Assemble each block group in a PUMA from the MABLE/Geocorr database. In a small percentage of cases, a block group is split between multiple PUMAs. In such cases, the summary totals are reduced by the proportion of the block group's households in the PUMA. This information is also available from the MABLE/Geocorr database.

**Step Two** Collect the marginal STF-3A tables for the block groups in the PUMA.

\_

<sup>&</sup>lt;sup>6</sup> See Footnote 3.

**Step Three** Construct from the PUMS a multiway demographic table that matches the demographics from the STF-3A tables for the corresponding PUMA. The entries of this table are the sums of the household weights from the PUMS.

Step Four •

- Add the marginal tables for all the block groups in the PUMA.
- Estimate a multiway table for the entire PUMA by using an IPF fit of this summed table to the PUMS.

- **Step Five** Use the estimate table as an additional marginal table.
  - Create an (m+1)-dimensional table.

The first m dimensions are the m marginals from STF-3A, whereas the  $m+1^{st}$  marginal is created by stacking all of the marginal tables. This (m+1)-dimensional stacked table, along with the table estimated from the sums, are the marginal tables used in an IPF procedure to an (m+1)dimensional table consisting entirely of ones. This results in an estimated multiway table for each block group in the PUMA. More information on this process can be found in the paper by Beckman, Baggerly, and McKay<sup>7</sup>.

In a forecast setting, Step Six is executed; otherwise, it is skipped.

#### Step Six

- Combine the block group estimates from the step above to form one multidimensional array.
- Using iterative proportional fitting, fit sets of forecast marginals against the multidimensional array—one block group at a time.

Forecasted populations for TRANSIMS are generated using a modification of the procedures given in the paper by Beckman, Baggerly, and McKay<sup>8</sup>. The technology's user must supply the algorithm with the STF-3A and PUMS data for the base year as required by Beckman, Baggerly, and McKay, which is shown in the five steps above. Additionally, the user must supply a set of summary demographics, such as age of the householder and household income, for the households in each block group in the projected year.

To forecast a population given projected STF-3A type marginal data on a census block group basis for the entire region, one starts with an individual PUMA. At the end of Step Five, three multidimensional arrays have been estimated for each census block group in the PUMA. The

<sup>&</sup>lt;sup>7</sup> See Footnote 3.

<sup>&</sup>lt;sup>8</sup> See Footnote 3.

dimensions of the three tables or arrays (one for family households, one for non-family households and one for those living in group quarters) represent particular demographic types. The entries in the arrays are the proportions of households of the various demographic types generated in the complete baseline procedure.

For family households, the array has five demographic dimensions:

- householder's age,
- family income,
- number of workers in the family,
- type of family, and
- householder's race.

The non-family array or table is also indexed by five demographic variables:

- household type,
- race of the householder,
- age of the householder,
- gender of the householder, and
- household income.

Group quarters arrays are two dimensional and represent:

- type of group quarters, and
- age of the individuals.

In general, let the proportions in the arrays or tables be denoted by the following:

- ${}^{f}p_{i,j,k,l,m}$  for a family array
- ${}^{n}p_{i,j,k,l,m}$  for a non-family array
- ${}^gp_{i,j}$  for group quarters

The forecast procedure proceeds as follows. The block groups in the PUMA that have the maximum number non-zeros in the estimated proportion arrays are identified. Of these, the block group with the largest number of households is selected. For this block group, the proportions of family households, non-family households, and group quarter residents are denoted by  $w^f$ ,  $w^n$  and  $w^g$ , respectively. In the second step, an array, H, with dimensions equal to the number of forecast demographics, is created.

<sup>&</sup>lt;sup>9</sup> See Footnote 3.

<sup>&</sup>lt;sup>10</sup> See Footnote 3.

In Portland, these demographics are the size of the household, the age of the householder, and the household income. Without loss of generality, we consider only these three demographics here. That is, we compute the array  $H_{P,A,I}$ .

 $H_{PAJ}$  is computed in the following steps. For each sample in the PUMS:

- 1) Determine if the house is a family, non-family, or a group quarter resident. Here, we assume the household under question is a family household.
- 2) For this family household, ascertain the five demographic indexes. Assume that these are 1,3,2,4,5.
- 3) Determine the indexes for the forecast demographics P,A,I. Assume here that these are p,a,i.
- 4) Let WT be the household weight given in the PUMS.

To compute a set of cross-classified proportions for each block group in the PUMA, we use the array  $H_{P,A,I}$  and iterative proportional fitting as described by Beckman, Baggerly, and McKay<sup>9</sup>. The forecast marginal demographics, household size, age of the householder, and household income for Portland are fit against the array  $H_{P,A,I}$  using iterative proportional fitting. The result is a three-dimensional array of proportions for the block group. The final set in the procedure is to select households from the PUMS according to these proportions as described in the Beckman, Baggerly, and McKay<sup>10</sup> paper.

In cases in which the cross-classified forecast proportions of the demographics rather than the marginal distributions are given, the households are drawn directly from the PUMS according to these proportions. The array  $H_{P,A,I}$  and the corresponding iterative proportional fit are not computed.

**Step Seven** Draw random households from the PUMS that match the demographics of each of the cells of the estimated multiway table for each block group.

# 4.5 Synthetic Households

Multiple demographics from STF-3A are used to create the baseline synthetic population. Synthetic households are divided into three categories:

- Family Households Households with two or more related individuals.
- Non-family Households Individuals living alone or unrelated individuals living together.
- Group Quarters Dwellings such as college dormitories.

# 4.5.1 Family Households

Because travel activity can depend on the household type, a baseline synthetic population of households and group quarters is generated for each of the three types. Family households are considered first. The summary tables in STF-3A that concern family households are as follows:

- P24 Age of the Householder
- P107 Family Income
- P112 Number of Workers in the Family
- P124A&B Poverty Status (which is not used here)
   \* Race \* Family Type \* Presence and Age of Children

Not all categories that are given for the above STF-3A tables are used in the procedure. For example, there are 25 categories of income in table P107. These are collapsed to seven categories. The census STF-3A table P124 (A & B) is used to create a race by using a family class summary table. Data in the categories of (1) below the poverty level, and (2) above the poverty level were added to give the resulting 12 family types:

Married Couple	Children under age 5 only
Married Couple	All children between 5 and 17
Married Couple	Children under 5 and 5 to 17
Married Couple	No children under 18
Male Householder	No wife present; children under age 5 only
Male Householder	No wife present; all children between 5 and 17
Male Householder	No wife present; children under 5 and 5 to 17
Male Householder	No wife present; no children under 18
Female Householder	No husband present; children under age 5 only
Female Householder	No husband present; all children between 5 and 17
Female Householder	No husband present; children under 5 and 5 to 17
Female Householder	No husband present; no children under 18

# 4.5.2 Non-family Households

Summary tables in STF-3A for non-family households are as follows:

- P17 Household Type and Relationship
- P20 Race \* Household Type \* Presence and Age of Children (The race of non-family householders can be derived from this table.)
- P24 Age of Non-family Householder
- P110 Non-family Household Income
- P127 Poverty Status (not used here) \* Age of Householder \* Household Type

# 4.5.3 Group Quarters

There are only two summary tables for group quarters in STF-3A:

- P40 Group Quarters
- P41 Group Quarters \* Age

# 4.6 Adjusting the IPF Routine

Minor adjustments must be made to the IPF routine to handle marginal summaries in table form. For example, two-way marginals (such as the race \* family class table given Section 1.2.4) are considered to be one marginal by the IPF routine. Such marginal tables are converted to a single demographic whose categories consist of all the combinations of the two demographics involved.

If two marginal tables contain a common demographic variable (e.g., the alone/not alone demographic in tables P17 and P127), the procedure is not altered and the fitting proceeds as above, treating each marginal separately.

In cases in which one demographic variable is in two summary tables (a one-dimensional table and a two-dimensional table) and has fewer categories in the two-dimensional table (e.g., STF-3A summary tables P24 and P127), an additional step is required. The procedure uses only one marginal table at a time. When the table with the *collapsed* marginal is considered, the procedure updates the cells as usual where all of the cells that contribute to the individual collapsed categories are updated by the same proportion.

# 4.7 Locating and Numbering the Population; Assigning Vehicle Emissions Type

The baseline synthetic population is produced on a block-group basis—no other information about the location of individual households is known. To place each household on the transportation network, procedures are developed using land-use data.

The number of vehicles owned by each household is given in the PUMS and is, therefore, in the synthetic population.

The Emissions Estimator module, which is described in Chapter Seven, requires that the vehicles be identified by emissions type. However, the emissions type of the vehicles in the household is unknown. The Population Synthesizer contains a model to assign vehicle types to each vehicle in the population. The last step in the creation of the synthetic population is to assign a unique number to each household and each person in the population.

# 4.7.1 Activity Location

Each household in the population is located at an activity location in the TRANSIMS Network. These are usually on the *walk* portion of the network.

Each network is required to have an *Activity Location* file. This file contains the locations of those places on the network in which activities may take place. Associated with these locations is a set of land-use characteristics that indicate the type of activities that may take place at that location.

Each network has a unique set of land-use characteristics associated with its activity locations. Land use is used to form a weighting factor for each activity location that represents the relative likelihood of a housing unit being placed there. The exact formulation of these weights depends on the network under investigation and the availability of land-use information. For a network representing a real metropolitan area, the land use could, for example, contain the square footage of single-family residential housing along with the square footage of multifamily housing that surrounds the activity location.

In this case, the weights for the activity locations could be formed by adding the square footage of single-family residential housing to a multiple of the square footage of multifamily housing (e.g., 10).

#### 4.7.1.1 Placing Households on Activity Locations

Given the housing weights associated with each activity location on the network, households are placed on these locations by taking the steps outlined below.

- **Step One** Identify all activity locations within a block group.
  - Assume that there are *n* of them.
  - Denote the associated household weights for these activities by  $w_I$ .
  - Compute the probabilities as follows:  $p_i = w_i/\Sigma w_I$ .

- **Step Two** Assign each individual household in the block group to one of the n activity locations according to the probabilities,  $p_I$ 
  - The location of the households is one of the required demographics for each synthetic household.

#### 4.7.2 Vehicles and Their Emissions

Each synthetic household is created with a number of vehicles assigned to it. These vehicles have a unique number and are identified as belonging to the household.

Assigned to each vehicle in the population is one of the vehicle emission types, which are described in Chapter Seven of this volume. This assignment may be done at random according to either a national or local distribution of vehicle emission types.

Each vehicle is also assigned a starting location, which consists of one of the parking locations on the driving network. Traditionally, this location has been the parking location closest to the household location. This information is written to the vehicle file.

# 4.7.3 Assigning Identification Numbers

The final step in generating a synthetic population is to assign a unique number to each household and person in the population. The person number is a unique identifier carried through the Route Planner to the Traffic Microsimulator. All output that is personoriented references these numbers.

Each vehicle driver in TRANSIMS must have an entry in the synthetic population. Therefore, fictitious individuals are added to the population to represent those who travel on the network but do not live in the area undergoing study. Known as "itinerant travelers," these are added to the synthetic population as single-person households, each with one vehicle. The same is true for transit drivers and freight haulers.

These households, along with the individual, are given their own unique household and person number. If demographics are added to the actual synthetic persons or households, the same demographics must be added to the itinerant traveler population. In some cases, these may be meaningless numbers because the activity list for these travelers is generated from origin-destination tables independent of the individual's demographics.

In equity studies, itinerant travelers can be viewed as a separate population. Every itinerant traveler owns one vehicle. The vehicle is given a unique number and type and is placed in the vehicle file. The starting location of these vehicles is the parking location where the traveler's trip begins. These starting points are most likely on the boundary of the study area, as itinerant travelers are those that are passing through the area or entering the area from the outside.

# 5. Using the Population Synthesizer

# 5.1 Overview

The Population Synthesizer module contains several programs that are executed in order. The module prepares files used by the subsequent modules.

# 5.2 Assembling the Required Input Data to Generate a Synthetic Population

- Sample input data are supplied with the TRANSIMS-1.1 software in *TRANSIMS\_HOME/data/synpop*. You may use these data or go through the general procedure described here to obtain similar data. Be aware that the population data must correspond with the supplied transportation network data to complete subsequent tasks in the TRANSIMS analysis process. Use the general procedure advisedly.
- PUMS and STF-3A data are available on CD-ROM from the Census Bureau.
- MABLE/Geocorr data are obtained from the following Internet site: <a href="http://plue.sedac.ciesin.org/plue/geocorr/">http://plue.sedac.ciesin.org/plue/geocorr/</a>.
- A file containing the marginal distributions of household size, householder age, and household income as a function of block group must be created or obtained if a population is to be forecasted.

# 5.2.1 Obtaining MABLE/Geocorr Data

Before running the Population Synthesizer, obtain the MABLE/Geocorr data from an Internet browser. Perform the following steps to generate a MABLE data file:

**Step One** Go to the MABLE/Geocorr web site and select a state.

**Step Two** Select the source and destination Geocode data (see Fig. 5 and Fig. 6).

**Step Three** For weighting variable, select Population (1900 Census).

Do **not** check the box *Ignore Census Blocks* (see Fig. 7).

**Step Four** Select Comma Separated Value File→Codes and Names

(see Fig. 8). No additional output options are required.

**Step Five** Click [Run Request]. The web server will require several minutes to

generate the file. When it is finished, a page with a geocorr.csv link will

be displayed.

**Step Six** Click on the link to view the MABLE data.

**Step Seven** After the data have downloaded, use your browser's *Save File* feature to save the data to disk. It is advisable to save the file with a meaningful name, such as *NewMexico\_MABLE.csv*. The filename extension must be .csv.

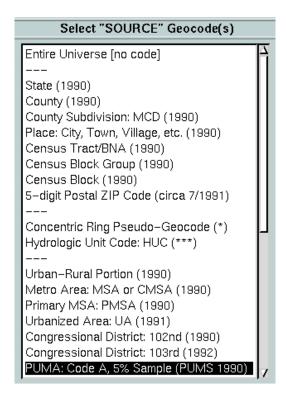

Fig. 5. The Select "SOURCE" Geocode(s) window.

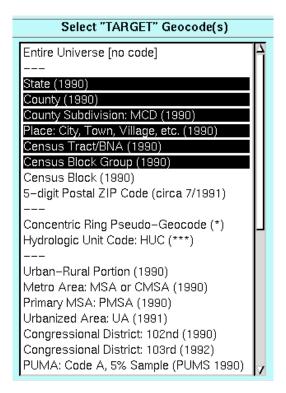

Fig. 6. The Select "TARGET" Geocode(s) window.

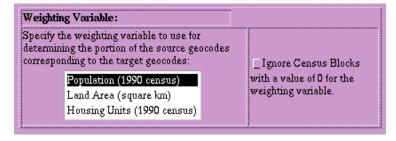

Fig. 7. The Weighting Variable window.

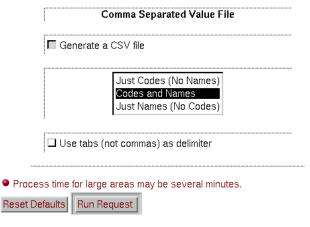

Fig. 8. The Comma-Separated Value File window.

# 5.3 Running the Population Synthesizer

To run the Population Synthesizer, use the following command line:

```
% Syn example.config
```

where example.config is the configuration file to be used. Appendix A provides an explanation of the configuration file keys.

# 5.3.1 Multiple PUMS

Although the Population Synthesizer will process multiple PUMS in a single run, we advise running it separately for each PUMS of interest. Some of the correlation structure within PUMS records is lost when PUMS are processed together.

# 5.3.2 Memory Load

The iterative proportional fitting computational process requires a fairly large amount of memory. The Population Synthesizer was run on PUMAS 01000, 01200, 01300, 01400, and 01500 for urban area 6442 (Portland—Vancouver, OR—WA (pt.): FIPS.STATE=41, URBAREA=6442); the running process required 110.6 MB of memory at its peak usage. For this reason, it is advisable to run one PUMA at a time for areas of interest.

The synthetic population output files are large as well. For the above-mentioned case,

- the family synthetic population file was 67.4 MB,
- the non-family file was 13.2 MB, and
- the group quarters file was 0.9 MB.

The processing time for this set of PUMAs was approximately four hours from start to finish, again on a 266 MHz Pentium machine running Linux.

Following the execution of the Population Synthesizer to produce three output files, these three files can be concatenated into a single file before locating the population and assigning household and person IDs using the *BlockGroupLoc* utility. Use a text editor to remove the two header lines from the second and third files, then append each file to the first file. The resulting concatenated file will be used as an input file for the *BlockGroupLoc* utility. The *Vehgen* utility described in the following section and the Activity Generator use the located population file produced by *BlockGroupLoc*.

# 5.4 Locating a Population on a Transportation Network

The *BlockGroupLoc* utility generates home locations for populations on a transportation network by correlating census tract and block group user data values specified in the network activity location file with tract and block group data in the baseline population. Candidate home locations must have the same census tract and block group as the household; they also must have residential land-use values greater than zero.

Some households may be in block groups that do not have any activity locations on the transportation network that are associated with that block group. Alternative tract and block groups may be specified for these households. The alternative tract/block group pairs are specified in a Tract/Block Group Substitution file.

*BlockGroupLoc* also generates household and person IDs and assigns them to the located population. The user data in the activity location table in the TRANSIMS transportation network must contain tract, block group, and residential and commercial land use values.

#### Format:

```
BlockGroupLoc <configuration file>
```

*BlockGroupLoc* uses configuration file keys from the TRANSIMS configuration file. Some keys have default values that may be used if the key is not specified in the configuration file. Appendix B lists these configuration file keys.

# 5.5 Generating a TRANSIMS Vehicle File for Located Synthetic Populations

A TRANSIMS vehicle file contains information about the initial locations of a household's vehicles. For most households, the starting location of the vehicle will be the parking location near the household's home location.

*Vehgen* is a utility that creates a TRANSIMS vehicle file containing information about the household's vehicles and their starting locations.

Each vehicle's starting parking location is found by iterating through the process links connected to the home activity location. Every home activity location must have at least one parking location accessible via the activity location's process links.

#### Format:

```
Vehgen <configuration file>
```

*Vehgen* uses configuration file keys from the TRANSIMS configuration file. Some keys have default values that may be used if the key is not specified in the configuration file. Appendix C lists these configuration file keys.

# 6. FILES

# 6.1 Population File

As previously discussed, the TRANSIMS baseline synthetic population system is designed to produce three principal types of populations: family households, non-family households, and group quarters. These populations are statistically equivalent to actual populations when compared at the level of block group or higher. In the forecast population, the family, non-family, and group quarters distinction is not made. The synthetic population file contains two header lines followed by the data lines.

#### 6.1.1 Header Lines

- The first line of the file contains the names of the household demographics in the population.
- The second line of the file contains the names of the person demographics in the population.

#### Format:

```
<text>: <description demog/data1> ... <description demog/dataN>
```

The <text> entry may be any text comment that is meaningful to the user. The <text> entry must be followed by a colon (:). A single word description of each of the optional household demographics in the file follows the colon.

Each optional household data item present in the household data lines of the file must have a single word description in the household header line (line 1 of the file). Each person demographic that is present in the person data lines of the file must have a single word description in the person demographic line (line 2 of the file). The single word description must not contain white space.

#### Example:

```
Household Demographics: PUMSHH R18UNDR RWRKR89 RHHINC Person Demographics: AGE RELAT1 SEX WORK89
```

The household data lines in a file with this header will have four optional household demographic values (PUMSHH, R18UNDR, RWRKR89, and RHHINC). The individual data lines in a file with this header will have four person demographic values (AGE, RELAT1, SEX, and WORK89). A complete list of possible demographics is found in Appendix D (Valid person and household demographic field names).

#### 6.1.2 Data Lines

For a single synthetic household, the data span multiple lines of the synthetic population file.

#### Format:

The first line of a household record contains the following household data:

```
<TRACT ID> <Blck Grp ID> H <TRANSIMS HH ID> <# persons> <# vehicles> <Home location> [<HHData1> ... <HHData2>]
```

<TRACT ID> and <Blck Grp ID> are the census tract and block group numbers. The tract numbers are represented as an integer with the following characteristics:

- Tract number 1 or 1.00 is represented as 000100.
- Tract number 1.01 is represented as 000101.
- The block groups retain their integer value.

The home location is the ID of the home activity location on a TRANSIMS Network. A value of -1 may be used if the home location is not yet known. Every household eventually must be assigned a home location of a TRANSIMS activity location before using TRANSIMS modules.

Following the household data are N lines of person data, where N = number of persons in the household.

```
<TRANSIMS HH ID> P <TRANSIMS Person ID> [PersonDemog1> ... <PersonDemogN>]
```

The household and person demographics/data in the file, both number and type of the data, depend on the demographics used to generate the population.

#### Example:

Household 1000 has four persons, two autos, home location of 1253, and demographics of PUMSHH (17643), R18UNDR (1), RWRKR89 (3), and RHHINC (38800). Person demographics for each member of the household are AGE, RELAT1, SEX, and WORK89.

```
Household Demographics: PUMSHH R18UNDR RWRKR89 RHHINC Person Demographics: AGE RELAT1 SEX WORK89 00001 00002 H 1000 4 2 1253 17643 1 3 38800 1000 P 101 38 0 0 1 1000 P 102 36 1 1 1 1000 P 103 7 2 1 0 1000 P 104 4 2 1 0
```

# 6.2 Tract/Block Group Substitution File

Block groups are located at activity locations on a transportation network based on the census tract and block group associated with the activity location in the network Activity Location Table. When locating a population on a sparse transportation network, some census tract/block groups may not have any associated activity locations.

The Tract/Block Group Substitution File enables users to specify a list of alternate census tract/block group pairs that can be used to identify candidate activity locations where the households in the missing tract/block group can be located.

The Block Group Locator uses the Tract/Block Group Substitution File to identify candidate home locations for households whose tract/block group is not found in any on the transportation network. The home location is selected from the activity locations that match the alternative tract/block pairs that are specified in the file. The TRANSIMS configuration file key, POP\_NEAREST\_BG\_FILE, is used to specify the name of the Tract/Block Group Substitution File to the Block Group Locator. The file format contains one header line followed by the data lines.

#### 6.2.1 Header Lines

The first line of the file contains the column header TRACT and BG followed by TRACT-1 BG-1 ... TRACT-n BG-n, where n is the number of alternate tract/block groups that will be specified. The fields in the line are white-space delimited.

```
TRACT BG TRACT-1 BG-1 ... TRACT-n BG-n
```

#### Example:

```
TRACT BG TRACT-1 BG-1 TRACT-2 BG-2 TRACT-3 BG-3 TRACT-4 BG-4
```

#### 6.2.2 Data Lines

The data lines in the file have the census tract and block group of the missing tract/bg pair followed by a list of alternate census tract/block group pairs:

<tract id> <block group> <alternate tract 1> <alternate block group 1> ... <alternate tract N> <alternate block group N>

#### Example:

```
1000 6 1000 5 1000 4 1000 7 1000 8
```

Tract 1000/block group 6 is not found in the activity location file. Activity locations from tract 1000/block group 5, tract 1000/block group 4, tract 1000/block group 7, and tract 1000/block group 8 can be used as candidate home locations for households in tract 1000/block group 6.

# 6.3 Forecast Marginal File

The file has no header and each line represents a single census block group. The following fields must be present in this order:

- TRACT The census tract number in a decimal format—leading or trailing zeros are allowed.
  - BG | The census block group number.
  - H1 The number of households containing one person.
  - H2 The number of households containing two people.
  - H3 The number of households containing three people
  - H4 The number of households containing four people.
  - H5 The number of households containing five people.
  - H6 The number of households containing six people.
  - H7 The number of households containing seven or more people.
  - A1 The number of households whose head is less than 24 years old or younger.
  - A2 The number of households whose head is between 25 and 34 years old.
  - A3 The number of households whose head is between 35 and 44 years old.
  - A4 The number of households whose head is between 45 and 54 years old.
  - A5 The number of households whose head is between 55 and 64 years old.
  - A6 The number of households whose head is between 65 and 74 years old.
  - A7 The number of households whose head is 75 years old or older.
  - II The number of households with annual income at or below \$4,999.
  - I2 The number of households with annual income between \$5,000 and \$9,999.
  - The number of households with annual income between \$10,000 and \$14.999.
  - I4 The number of households with annual income between \$15,000 and \$24,999.
  - The number of households with annual income between \$25,000 and \$34,999.
  - The number of households with annual income between \$35,000 and \$49,999.
  - The number of households with annual income between \$50,000 and \$74,999.
  - The number of households with annual income between \$75,000 and \$99,999.
  - I9 The number of households with annual income at or above \$100,000.

These fields can be separated by spaces or tab characters. The sums H1 + H2 + H3 + H4 + H5 + H6 + H7, A1 + A2 + A3 + A4 + A5 + A6 + A7, and I1 + I2 + I3 + I4 + I5 + I6 + I7 + I8 + I9 should be identical, and there should not be any records where this sum is zero.

#### Example:

```
13.01 1 187 112 44 49 5 0 6 59 95 87 62 80 18 2 76 48 75 39 44 58 32 31 0

# 6.4 Library Files

Table 9 shows synthetic population library files.

Table 9. Synthetic population library files.

Type	Filename	Description	
Binary Files	libTIO.a	The TRANSIMS Interfaces library.	
Source Files	synpopio.h	The synthetic population data structures and interface functions.	
	synpopio.c	The synthetic population interface functions source file.	

Volume Three—Modules 08 January 2003 33

# Appendix A: Synthetic Population Configuration File Keys

Configuration File Key	Description
SYNPOP_BASE_DIRECTORY	\$TRANSIMS_HOME
SYNPOP_BASE_PREFIX	The filename prefix for the base-synthesized
	population output files. No base-year output will be
	generated if this key is blank.
SYNPOP_FORECAST_PREFIX	The filename prefix for the forecast-synthesized
	population output files. No forecast output will be
	generated if this key is blank.
SYNPOP_HOUSEHOLD_DEMOGRAPHICS	The list of household PUMS fields to be placed in
	the population output files (separated by
	semicolons). See the file
	\$TRANSIMS_HOME/data/synpop/docs/pumsusdd.txt
	for a complete of the possible fields.
SYNPOP_KEEP_TEMP_FILES	Whether to retain the working files after the
	population synthesis is complete (1 = yes, 0 = no).
SYNPOP_MABLE_FILE	The directory in which the MABLE output file is
	stored.
SYNPOP_MARGINALS_FILE	The location of the Forecast Marginals file.
SYNPOP_PERSON_DEMOGRAPHICS	The list of person PUMS fields to be placed in the
	population output files (separated by semicolons).
	See the file
	\$TRANSIMS_HOME/data/synpop/docs/pumsusdd.txt
GINIDOD DIMIG	for a complete list of the possible fields.
SYNPOP_PUMAS	The list of five-digit PUMA numbers to be
GUNIDOD DUMG DIDUGEODY	processed (separated by semicolons).
SYNPOP_PUMS_DIRECTORY	The directory in which the PUMS data are stored.
SYNPOP_RANDOM_SEED	The random number seed (integer).
SYNPOP_STATE	The two-letter abbreviation (lowercase) of the state of interest.
SYNPOP_STF_DATA_DIRECTORY	The directory in which the STF3A dBase files are located.
SYNPOP_STF_INFO_DIRECTORY	\$TRANSIMS HOME/data/synpop/Parep2/stf
SYNPOP TEMP DIRECTORY	The directory in which temporary working files
SINFOP_IEMP_DIRECTORI	will be placed.
	will be placed.

Volume Three—Modules 08 January 2003 34

#### Appendix B: BlockGroupLoc Configuration File Keys

Configuration File Key	Description
ACT_BLOCKGROUP_HEADER	The user data column header in the network activity location file used to specify the block group.  Default = BG
ACT_HOME_HEADER	The user data column header in the network activity location file used to specify single family home locations. Default = HOME
ACT_MULTI_FAMILY_HEADER	The user data column header in the network activity location file used to specify multifamily home locations. If not specified, multifamily user data from the activity location file is ignored.
ACT_TRACT_HEADER	The user data column header in the network activity location file used to specify the census tract.  Default = TRACT
NET_ACTIVITY_LOCATION_TABLE*	The network activity location table name.
NET_DIRECTORY*	The directory where the network files reside.
NET_LINK_TABLE*	The network link table name.
NET_NODE_TABLE*	The network node table name.
POP_BASELINE_FILE*	The name of the file containing the baseline population.
POP_LOCATED_FILE*	The name of the file where the located population will be written.
POP_NEAREST_BG_FILE	The name of the Tract/Block Group Substitution file that contains information about the nearest tract/block group for block groups that have no activity locations on the transportation network.
POP_RANDOM_SEED	The random number seed (integer). Default = 985456379
POP_STARTING_HH_ID	The number from which the generated households will be sequentially numbered. Default = 1
POP_STARTING_PERSON_ID	The number from which the generated persons will be sequentially numbered. Default = 101

• Configuration file keys required for *BlockGroupLoc*. All others are optional and will use default values.

### Appendix C: Vehgen Configuration File Keys

Configuration File Key	Description
POP_STARTING_VEHICLE_ID	The number from which the generated vehicles will be sequentially numbered.  Default = 100
VEH_VEHICLE_TYPE	The TRANSIMS vehicle type that will be used for all generated vehicles. Must correspond to the types defined in the network in file <i>Id.h</i> . Default = 1 (auto)
VEH_VEHICLE_SUBTYPE	An integer value to specify a vehicle subtype that can be used to partition vehicles for emissions studies. Default = 0
VEH_GENERATE_FOR_DRIVERS	Boolean value that controls the method used by the vehicle generator to produce the vehicles for a household.  Value = 1 generates a vehicle for every person in the household whose age is ≥ the value specified by the configuration file key  VEH_DRIVER_MINIMUM_AGE.  Value = 0 generates the number of vehicles as specified by the household demographics.  Default = 0
VEH_DRIVER_MINIMUM_AGE	The minimum age of a driver. Used to determine the number of persons eligible for a vehicle.  Default = 16
VEH_RANDOM_SEED	The seed for the random number stream. Default = 985456379
VEH_AGE_DEMOGRAPHIC	The header that denotes the age demographic in the population file. Default = AGE.
VEHICLE_FILE	The name of the TRANSIMS vehicle file for the population.

# Appendix D: Valid Person and Household Demographic Field Names

Following is a list of the demographic options that are available for households and the allowed values for each demographic item.

#### Appendix E: Block Group Locator Error Codes

Error codes for the Block Group Locator are in the range 24000 – 24999.

Code	Description
24001	Caught signal.
24002	Assertion failed.
24003	Exception has occurred.
24004	Network exception has occurred.
24005	Unknown exception has occurred.
24006	Invalid program usage.
24007	Failed to open file for reading.
24008	Failed to open file for writing.
24009	Mandatory configuration key not specified.
24010	Failed to read record from file.
24011	Memory allocation failed.
24012	Mandatory file not specified.
24013	Failed to construct network.
24014	No user data for specified header in network activity location table.
24015	Insufficient data in network table.

#### Appendix F: Population Synthesizer Error Codes

Error codes for the Population Synthesizer are in the range 27000 – 27999.

Code	Description
27001	Caught signal.
27002	Assertion failed.
27003	Incorrect command line.
27004	Missing configuration key.
27005	Unable to open file.
27006	Invalid data in file.
27007	Rake code failed.
27008	Internal error.
27009	Database utility error.

## Appendix G: Vehicle Generator Error Codes

Error codes for the Vehicle Generator are in the range 33000 – 33999.

Code	Description
33001	Caught signal.
33002	Assertion failed.
33003	Exception has occurred.
33004	Network exception has occurred.
33005	Unknown exception has occurred.
33006	Invalid program usage.
33007	Failed to open file for reading.
33008	Failed to open file for writing.
33009	Failed to write record to file.
33010	Mandatory file not specified.
33011	Failed to construct network.
33012	Person demographic header not specified.
33013	Specified person demographic not found in population.
33014	Home activity location not found in network activity location table.
33015	Failed to read file header line(s).
33016	No parking location accessible via process links from specified activity location.

#### Chapter Two: Index
